## Abstract

Important factor of engineering provision is building military bridges over obstacles, the bridges being of three types according to their functions: temporary bridges being built in communication zones; rapidly layable, the so called escort bridges implemented on troops displacement routs; and rapidly layable deployable mechanical bridges directly usable in military situations that can very successfully be used in civil conditions, extreme situations and in emergency circumstances alike. The present work touches upon a topical problem – to develop deployable mechanized bridges of a bigger span of 32÷48 meters and their bridgelayers in comparison with conventional assault bridges and their bridgelayers which enable to lay a bridge over an obstacle of 22÷30 meters in width in 3-7 minutes by means of a stowed package of 12÷16 meters in length that is placed on a single vehicular means – bridgelayers, without the crew having to exit the armored tank

The mentioned task can be fulfilled with staged approach, with the application of transformable systems theory based on double and triple type transformations of shaping by deployment-folding, instead of a single type transformations realized in conventional assault bridges, no matter what method is used for laying them over an obstacle - whether it is “putting on” or “inverting”.

At the first stage, assault bridges based on two types of transformation are considered at the initial stage.

The deployable bridge construction based on the “folding principle”+”telescope principle” of shaping is characterized by high quality. It enables to assume a 48 meters bridge by deploying the folded transport package of which sizes correspond to the sizes of existing folded military bridges.

Besides, the mentioned bridges have multiple cylindrical units, that is disadvantageous in battle situations, and their stiffness against bending is relatively low in longitudinal direction, which can be regarded as serious drawback as well.

Thus at the further stage, a task of developing a deployable bridge that would have high stiffness load-bearing elements playing a role of main mechanisms of the system transformation at the deployment stage was set, where the elements would have to be load-bearing ones of the upper running part and chord of the bridge at the final stage of transformation when a fixed operation shape of the transformable system is assumed.

Based on these requirements, a deployable bridge construction by application of “folding”+”rolling” approach of shaping has been developed. The work overviews general designs of the bridge, its calculation and experimental study of the developed model of 4.8 meters in length.

The conducted complex studies revealed advantages of the bridge, conditioned by high-end technology of the bridge development. It should be noted that in case of enlarged span, approximately within the range of 38m÷48m, the height of the stowed transport package of the bridge increases, which leads to limiting the bridgelayers transportability. The bridgelayers construction that is developed on the tank basis is characterized by considerable height of mounting, which hampers the bridge to be blanked off, and the assembling of the lower rollable chord made of high stiffness cables became difficult.

In the modification of the bridge which is built on the base of “folding principle”+”folding principle”, many disadvantages were eliminated but the stowed transport package of the bridge still remained high.

The mentioned record-breaking length span bridges developed by systematic, step by step approach, completely fulfill the requirements of civil application by all their parameters. The work deals with the use of bridges and bridgelayers in forced operations only, which is regarded as an extremely difficult procedure in the military art and requires from a bridge and bridgelayer fulfilling special parameters. To this end, it was necessary to use the triple transformation approach for shaping instead of the double transformation approach, and a complex method - “putting on method” + “inverting method” of laying a deployable bridge developed by triple transformation approach over an obstacle was used for the purposes of developing the new bridgelayer.

By application of the mentioned transformation approaches and by classifying and systematizing the complex method of laying the bridge over an obstacle by a bridgelayer, basic modifications of a deployable mechanized assault bridgelayer and a 32÷48 m. span bridge were developed. The completely different kinematical design of the bridge requires use of two types of key complexes that are already used in modern bridge constructions, which is the advantage of the bridge kinetics due to the fact that manufacturability of the basic bridge is improved even more.

The developed bridge is manufactured by high stiffness aluminum alloy. The sizes of its stowed transport package are: width 4.1 m; length 12 m; and height is 2.6 which is very important. The bridge span is divided in the middle initially and then it is folded by mutually turning. When it is folded, the two parts of the bridge enter each other, and then, by displacement of the span edge parts, the bridge transport package attains its least sizes. The bridgelayer design which has been developed on the basis of the tank LEOPARD-2 is unusual and optimal. The bridge is mounted from a tank by displacing it ahead and then by resting the bridgelayer platform upon the ground and mounting the bridge in cantilever fashion. The process envisages all possible loads and fixing the bridge against overturning. The bridge weight is 19,5 tonnes.

The bridge can be transported and mounted also by a motorcar and helicopter which is very important in terms of use the basic bridge for civil purposes, and the mounting of assault bridges by a helicopter completely corresponds to the modern requirements of the military art.

არსებული ნაკლოვანებების აღმოფხვრის მიზნით დამუშავდა ახალი სქემა ხიდისა.

### V.3. გასაღები ხიდის ორმაგი ტრანსფორმაციის – “დაკევის პრინციპი” + “ტელესკოპის პრინციპი” სემინალი სქემა

მიუხედავად სხვადასხვა ვარიანტების სემინალისა, რომლებიც იქნებიან სასაუბროს 32÷48 მეტრი მალის მქონე გასაღები, საერიო მექანიზმული ხიდის სემინალი, ფორმალური სემინალის ორმაგი ტრანსფორმაციის პრინციპი სხვადასხვა კომბინაციებია, თუმცა მათში დაკევილი პაკეტი სიმართლის საგრძნობი შემცირება.

ამდენად, დაიწყო ძიება, გასაღები ხიდიდან სუფთა ტელესკოპის პრინციპი სემინალი ხიდის ანალოგიებია, რაც შემდგომში გახდება საფუძველი “დაკევის პრინციპი” + “ტელესკოპის პრინციპი” ხიდის კონსტრუქციული სემინალის სემინალის [38] [39] [40] [41].
